# INTRODUCTION

## 1.1 Background of Study

Tourism is an important contributor to Malaysia's economy through visitor arrivals, accommodation activities, tourism expenditure, transportation, food and beverage services, retail activities, and employment. The performance of the tourism sector can be assessed through different indicators such as tourist arrivals, visitor origin, transportation mode, hotel capacity, occupancy rate, visitor expenditure, and employment.

According to Tourism Malaysia, Malaysia recorded 37,961,485 visitor arrivals in 2024, representing a 31.1% increase from 2023, while visitor receipts reached RM106.78 billion, an increase of 43.7% compared with 2023. These figures demonstrate the strong recovery of the tourism sector following the COVID-19 pandemic.

However, tourism development is not necessarily distributed equally across Malaysia. Differences in visitor demand, accommodation capacity, infrastructure readiness, and economic benefits can result in some states experiencing stronger tourism activity than others. Therefore, data analytics can be used to identify tourism patterns, understand disparities, and support more informed tourism planning.

This project develops an interactive Power BI tourism dashboard to analyze Malaysia's tourism performance from the perspectives of visitor arrivals, accommodation, and economic contribution. In addition, machine learning forecasting and a strategic position matrix are incorporated to provide insights into future tourism demand and infrastructure readiness.

## 1.2 Problem Statement

Malaysia's tourism industry has experienced substantial recovery following the pandemic. Nevertheless, tourism growth is not even distributed across the country. Some states attract relatively high numbers of visitors and generate strong tourism activity, while other areas may have tourism potential, but face limitations related to accommodation capacity, infrastructure, and economic readiness.

The dashboard identifies this issue as “The Tourism Gap: Exploring Uneven Development Across Malaysia.” Without a clear understanding of these differences, tourism planning may concentrate resources in already-developed destinations while areas with tourism potential remain underdeveloped.

Another challenge is that tourism performance involves multiple interconnected indicators. Visitor arrivals alone cannot fully explain the economic performance of tourism. Accommodation utilization, visitor expenditure, and employment also need to be considered. For example, the dashboard records an average hotel occupancy rate of 42.66%, indicating that a considerable amount of available accommodation capacity remains unutilized.

Therefore, an integrated dashboard is required to combine tourism demand, accommodation performance, economic contribution, and future tourism trends to provide a clearer understanding of Malaysia's tourism development.

## 1.3 Objectives

- To Identify the trends, patterns, and geographical distributions of tourist arrivals in Malaysia.
- Determine the relationship between tourist arrivals and accommodation performance across Malaysian states.
- Discover how tourism expenditure and employment contribute to Malaysia's sustainable economic development.
- To forecast future tourist arrivals using machine learning and identify potential changes in tourism demand up to 2027.
- To develop an interactive Power BI dashboard that presents tourism trends, economic indicators, strategic insights, and recommendations to support the sustainable tourism industry in Malaysia.

# LITERATURE REVIEW

## 2.2 Tourist Arrivals and Tourism Demand

Tourist arrivals are one of the key indicators used to evaluate tourism demand and performance. Changes in visitor arrivals can provide an indication of tourism recovery, market demand, and changes in the attractiveness of a destination.

Tourism Malaysia reported that Malaysia received 37,961,485 foreign visitors in 2024, representing a 31.1% increase compared with 2023. Visitor expenditure also increased substantially, reaching approximately RM106.8 billion in 2024. Singapore remained the largest source market, followed by Indonesia and China.

The strong increase in visitor arrivals demonstrates the recovery of Malaysia's tourism sector following the COVID-19 pandemic. However, analyzing total arrivals alone does not provide information about how tourism demand is distributed geographically. Differences between states and source markets need to be examined to identify areas with relatively high or low tourism demand.

Therefore, the present study analyses tourist arrivals by year, state, nationality, visitor type, and mode of transport. The use of state-level arrival data provides a more detailed understanding of the geographical distribution of tourism demand across Malaysia.

## 2.3 Accommodation Performance and Tourism Demand

Accommodation is an important component of the tourism industry because hotels and other accommodation establishments provide capacity for visitors and support tourism-related economic activities. Hotel occupancy rate, number of accommodation establishments, number of guests, and average length of stay can be used to assess accommodation performance.

The relationship between visitor demand and accommodation capacity is particularly important because increasing tourist arrivals does not necessarily mean that accommodation resources are being utilized efficiently. A destination may experience high visitor demand while facing capacity constraints, whereas another destination may have substantial accommodation capacity but relatively low demand.

## 2.4 Tourism Expenditure and Employment

Tourism expenditure represents an important channel through which tourism generates

economic benefits. Visitor spending can support various industries, including accommodation, food and beverage, transportation, retail, entertainment, and other tourism-related services.

Employment is another important indicator of tourism's economic contribution. DOSM reported that tourism-related employment reached 3.7 million persons in 2025, with retail trade and food and beverage serving services representing major shares of tourism-related employment.

These findings support the inclusion of both tourism expenditure and employment in the Economic dashboard. Examining these indicators together can provide a more comprehensive understanding of how tourism contributes to economic activity beyond visitor numbers alone.

### 2.5 Tourism and Sustainable Economic Development

Sustainable tourism involves balancing tourism development with economic, social, and environmental considerations. From an economic perspective, sustainable tourism should generate economic benefits while supporting employment and maintaining the long-term viability of tourism-related businesses and destinations.

Recent research on Malaysia has examined the relationship between tourism, economic development, energy consumption, and environmental sustainability. Raihan et al. (2025) analyzed Malaysian time-series data from 1995 to 2020 and found relationships between tourist arrivals, tourism expenditure, tourism receipts, economic growth, energy consumption, and carbon emissions. Their findings indicate that tourism can contribute to economic growth while also creating environmental pressures, highlighting the importance of considering sustainability alongside tourism expansion.

This is relevant to the present project because increasing visitor numbers should not be considered the only measure of successful tourism development. The project therefore focuses particularly on economic sustainability, considering tourism demand together with accommodation utilization, expenditure, and employment.

## 2.6 Summary

The literature indicates that tourism performance should be evaluated using multiple dimensions rather than visitor arrivals alone. Tourist arrivals provide information about tourism demand, while accommodation indicators provide information about tourism capacity and utilization. Tourism expenditure and employment demonstrate the wider economic contribution of tourism.

Official Malaysian statistics also demonstrate the substantial economic importance of the tourism sector. At the same time, recent research highlights that tourism development can have both economic benefits and environmental implications. Therefore, sustainable tourism planning requires a balanced understanding of tourism growth and its broader impacts.

Based on these findings, this project integrates tourist arrivals, accommodation, tourism expenditure, employment, and future tourism demand within an interactive Power BI dashboard. This approach provides the foundation for analyzing Malaysia's tourism performance and identifying areas of uneven tourism development.

# METHODOLOGY

## 3.1 Data Collection

This project had collected and integrated tourism and economic datasets from several official Malaysian government sources, including the Department of Statistics Malaysia (DOSM), Tourism Malaysia, and data.gov.my. The datasets were selected to provide information on tourism expenditure, employment, transportation, accommodation, visitor arrivals, and Malaysia's overall economic performance across the year from 2019 to 2024.

The Tourism Satellite Account (TSA) 2025 published by the Department of Statistics Malaysia (DOSM) was used to obtain data related to the economic contribution of tourism. The dataset provides information on tourism expenditure, tourism employment, mode of transport, and accommodation. These variables were used to analyze the economic performance and contribution of tourism-related industries in Malaysia. In addition, Real GDP data from OpenDOSM was used to provide an economic context for analyzing tourism performance in relation to Malaysia's overall economic development.

Tourism Malaysia's Malaysia Tourism Key Performance Indicators (KPI) datasets for 2020, 2021, 2022, 2023, and 2024 were used to analyze visitor and accommodation performance. The datasets include indicators such as Tourist, Excursionist arrivals, average hotel occupancy rate, domestic visitors and foreign visitors.

The Monthly Arrivals by State of Entry, Nationality & Sex dataset from data.gov.my was used to analyze tourist arrivals according to year, state of entry, nationality, and sex. The dataset is produced from records in the Malaysian Immigration System (MyIMMs), which records arrivals and departures at Malaysia's international points of entry. The dataset contains variables including date, nationality, state of entry, total arrivals, male arrivals, and female arrivals.

The project integrates tourism-related datasets containing information on visitor arrivals, accommodation, expenditure, employment, and other tourism indicators. The main data categories used in the dashboard are:

| **Data Category** | **Main Variables / Indicators** |
|---|---|
| Tourist Arrivals | Year, country, state, visitor type, tourist arrivals |

| | |
|---|---|
| Transportation | Land, air, sea and rail arrivals |
| Accommodation | Hotels, hotel guests, hotel occupancy rate, average length of stay |
| Tourism Expenditure | Tourism products and expenditure by category |
| Employment | Tourism employment by industry and yearly employment growth |
| Strategic Analysis | Infrastructure readiness and tourism demand |
| Forecasting | Historical monthly tourist arrivals and ML forecast |

### 3.2 Data Preparation

The data preparation process was carried out using the Extract, Transform, and Load (ETL) approach to prepare the tourism datasets for analysis and visualization in Power BI. The ETL process consisted of three main stages: Extract, Transform, and Load. This process was used to integrate data from different sources, standardize the data structure, and produce consistent datasets for the development of the tourism dashboard.

#### 3.2.1 Extract

In the extraction stage, the required tourism datasets were collected from the identified official data sources. Google Colab was used to extract and initially process datasets before they were prepared for Power BI. The datasets consisted of tourism-related information such as tourist arrivals, accommodation, tourism expenditure, employment, and mode of transport. In particular, the tourist arrival data were obtained separately for different years. The yearly datasets were first imported into Google Colab to allow them to be processed using a consistent procedure.

#### 3.2.2 Transform

The transformation stage involved restructuring and standardizing the extracted datasets so that they could be used consistently for analysis. Several transformation procedures were performed using

Google Colab.

First of all, the structure of some datasets was changed by pivoting columns and rows. This was necessary because some source datasets were originally presented in a wide format that was not suitable for analysis. The data were reshaped into a more structured format where relevant variables were organized into rows and columns.

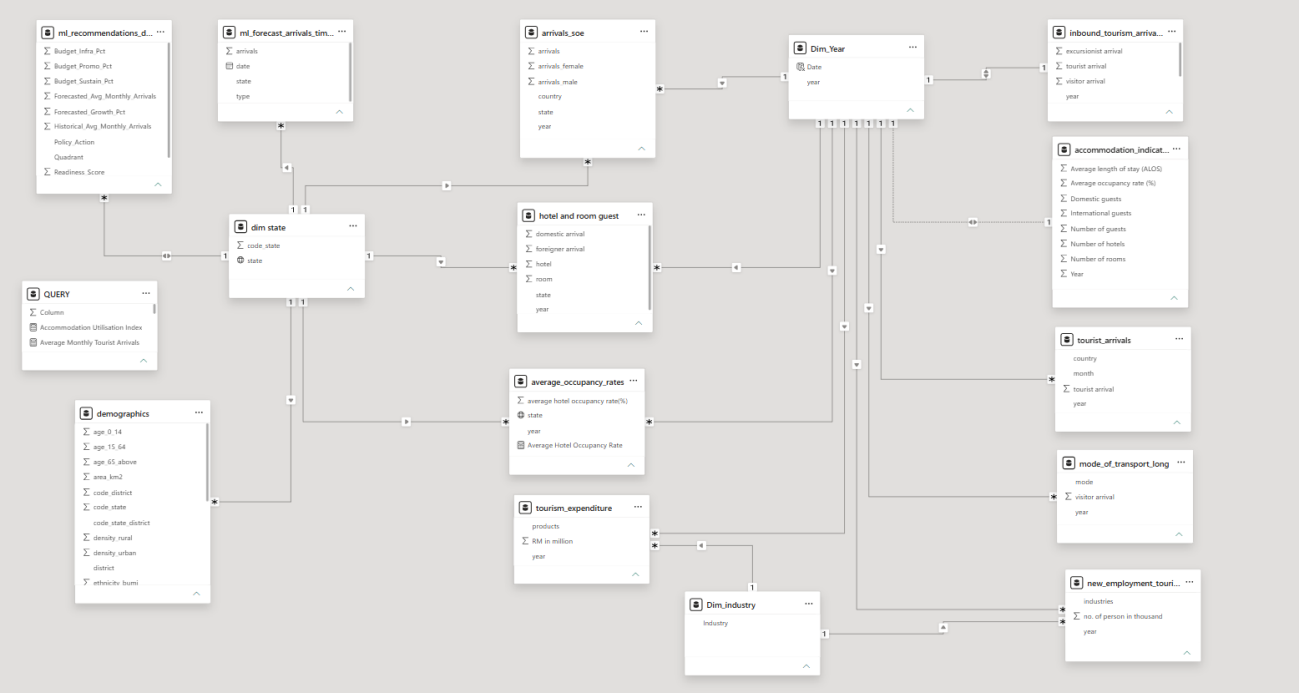

Second, the tourist arrival datasets from different years were combined into a single tourist arrival dataset. Instead of maintaining separate datasets for each year, the yearly datasets were appended together to create one consolidated dataset. This allowed tourist arrivals to be analyzed continuously across multiple years and simplified the data model in Power BI.

Third, variable names and categorical values were standardized to ensure consistency across datasets. For example, the state name “Kuala Lumpur” was standardized as “W.P. Kuala Lumpur”. Similar inconsistencies in state names and other categorical variables were standardized where necessary.

### 3.2.3 Load

After the transformation process was completed, the cleaned and standardized datasets were loaded into Microsoft Power BI for data modelling and visualization. The datasets were imported as individual tables according to their respective purposes. The Power BI data model was then structured by forming the required tables and establishing relationships between related tables. Common fields such as year, state, and other relevant dimensions were used to connect the datasets where appropriate.

### 3.3 Data Architecture

The project utilizes a multidimensional relational data model structured as a Galaxy Schema to integrate disparate datasets for seamless filtering and aggregation. This architecture ensures that spatial, temporal, and categorical dimensions dynamically cross-filter multiple independent quantitative fact tables, enabling complex multidimensional online analytical processing (OLAP).

To provide context and filtering capabilities, the model employs shared conformed dimension tables that store descriptive attributes used to slice, dice, and group the data. Dim_Year acts as the central time dimension, dim state serves as the primary geospatial dimension, and a categorical dimension, Dim_industry, is utilized specifically to filter employment data and track labor distribution across various economic sectors.

### 3.4 Data Modelling

The data modelling phase transforms raw mobility, accommodation, and economic datasets into a structured analytical framework to evaluate current tourism distribution and predict future carrying capacity risks. This process bridges historical visitor assessments with advanced machine learning forecasting to generate actionable insights for sustainable regional development.

#### 3.4.1 DAX Measures

Several Data Analysis Expressions (DAX) measures were created in Power BI to derive additional indicators from the original variables. These measures were developed to support the

analysis and provide more meaningful metrics for evaluating visitor arrivals, accommodation, expenditure, and employment. The created DAX measures are presented in the table below.

| No | DAX Measures | Purpose |
|---|---|---|
| 1 | Employment Contribution % | Calculates the proportion of jobs provided by specific tourism sub-sectors relative to the total tourism workforce. |
| 2 | Employment Growth % | Measures the year-over-year percentage change in tourism-related employment, tracking the post-crisis workforce recovery and identifying periods of contraction or stabilization. |
| 3 | Expenditure per Tourist (RM) | Determines the average financial yield per individual visitor by dividing total tourism expenditure by total tourist arrivals. |
| 4 | Tourism arrival Growth % | Computes the longitudinal percentage change in visitor volumes between selected time periods, enabling the assessment of post-2021 recovery trajectories and overall tourism demand trends. |
| 5 | Excursionists Bar Tourists Bar | Generates a matrix with data bars to scale the volume of day-tripping excursionists, allowing for direct visual comparison against overnight tourist volumes by transport mode. |
| 6 | ChatbotIframe | Embeds an HTML `<iframe>` element within the HTML Content visual to dynamically host the external Streamlit AI chatbot application, enabling real-time interactive natural language querying of VMY2026 tourism metrics directly on the report canvas. |

### 3.4.2 Predictive modelling

Machine learning time-series forecasting was applied to historical monthly tourist arrival data utilizing Meta Prophet and SARIMAX architectures in Python to project future visitor demand. This framework projects state-level monthly visitor volumes across the 2026–2027 Visit Malaysia Year period, establishing baseline arrival trajectories alongside 95% confidence bounds to account for seasonal patterns and market volatility. Within the Power BI dashboard, these predictive outputs are integrated into a continuous time-series visualization, wherein historical actuals are depicted using solid lines while future projections are represented by dotted trajectories bounded by shaded

confidence intervals, enabling clear visual differentiation between observed data and model projections.

To evaluate whether individual states possess the structural capacity to sustainably absorb projected tourist inflows, a secondary machine learning pipeline was constructed using scikit-learn. This methodology incorporates four key structural indicators: hotel room capacity, transport network density, tourism sector employment, and visitor expenditure per capita. These variables are normalized using MinMaxScaler to eliminate scale bias and subsequently aggregated via Principal Component Analysis (PCA) feature weighting. This process synthesizes the underlying multi-dimensional indicators into a composite Sustainable Infrastructure Readiness Score ranging from 0 to 100 for each state, providing a standardized benchmark of regional operational readiness.

By intersecting each state's projected arrival growth rate against its calculated readiness score on a strategic matrix, the analytical framework automatically categorizes regions into four actionable policy quadrants. States exhibiting high growth projections alongside low infrastructure readiness are classified under Overtourism Risk, signifying an urgent requirement for facility expansion and capacity management. Conversely, states demonstrating both elevated growth and strong readiness fall into Balanced Growth, serving as benchmark models for sustainable expansion. Regions characterized by high structural capacity, but lower growth trajectories are identified as Underutilized Potential, highlighting prime opportunities for targeted promotional initiatives. Finally, states presenting low metrics across both growth and readiness are categorized as Emerging / Low Priority, indicating a requirement for phased, long-term foundational infrastructure development.

### 3.4.3 Artificial Intelligence(AI) Chatbot

An AI chatbot was developed as an interactive assistant for the Malaysia Sustainable Tourism Power BI Dashboard. The chatbot, named VMY2026 AI Assistant, was designed to allow users to interact with the dashboard information through natural-language questions. It provides users with quick explanations and insights related to tourist arrivals, hotel occupancy, tourism expenditure, average length of stay, and future tourism demand.

The chatbot was developed using Python and Streamlit, which provides the interface for the conversational system. The Streamlit application was designed with a customized interface to match the purple theme of the Power BI dashboard, allowing the chatbot to be integrated as a complementary analytical tool. The interface consists of a chatbot header, conversation area, and text input field where

users can submit questions.

The chatbot uses the OpenAI Python client to communicate with the Gonka Router API, which provides access to the selected large language model, DeepSeek-V4-Flash-0731. A system prompt was created to provide the chatbot with the key tourism indicators used in the dashboard. These include total arrivals, number of hotels, tourism expenditure, average length of stay, transportation patterns, hotel occupancy, domestic tourism contribution, and the machine learning forecast towards 2027. This enables the chatbot to generate responses that are focused on the tourism indicators presented in the dashboard.

The chatbot also maintains conversation history using Streamlit's session_state. Previous user questions and chatbot responses are stored and included in subsequent API requests. This allows the chatbot to maintain conversational context rather than treating every question as an isolated query. For example, a user can first ask about hotel occupancy and subsequently ask a follow-up question about the implications of the occupancy rate.

# FINDINGS

## Arrivals

Visitor arrivals in Malaysia have shown strong recovery momentum, growing 31.67% overall after a near-total collapse in 2021 due to the outbreak of Covid-19, climbing back to approximately 25 million by 2024. Travelling by land remains the dominant mode of entry, accounting for 65.32% of arrivals, followed by air travel at 28.76%, while sea and rail contribute only a small fraction. Inbound arrivals are heavily weighted toward Singapore, which accounts for nearly 40 million visitors cumulatively. This surpasses secondary markets like Indonesia and China, demonstrating that regional proximity and land connectivity remain the primary engines of Malaysia's tourism market.

## Accommodation

Malaysia's accommodation sector heavily relies on domestic tourism, with local guests accounts for nearly 77.2% of total hotel visitors compared to just 22.8% from international visitors. Despite steady visitor growth, the national average hotel occupancy rate stands at only 42.66%, indicating notable surplus accommodation capacity. Among the states tracked, Pahang records the highest combined domestic and international hotel arrivals, positioning it as a standout performer relative to other states in terms of accommodation demand.

## Economics

Tourist spending is concentrated most heavily on country-specific tourism goods, which command 34.61% of total receipts ahead of accommodation and passenger transport. Interestingly, food & beverage and retail trade sectors generate more tourism-related employment than accommodation or transport do, highlighting significant indirect economic multipliers. Overall, total tourism expenditure reached RM445.21 billion, translating to roughly RM4360 spent per tourist. Employment trends closely mirrored the arrivals pattern, contracting sharply in 2020–2021, at -4.18% and -1.40% respectively due to the pandemic before rebounding to a peak growth of 4.88% in 2023 and stabilizing through 2025.

## Strategy/Forecast

Time-series forecasts indicate upward arrival trajectories extending through 2027, reinforcing the strategic objectives of the Visit Malaysia 2026 campaign. To translate these macro trends into actionable state-level policies, a composite Demand vs. Readiness matrix segment states into four key

profiles: Overtourism Risk, Underutilized Potential, Balanced Growth, and Emerging/Low Priority. This classification offers an analytical baseline to address infrastructure bottlenecks and optimize regional promotion efforts.

**Insights**

Malaysia's heavy reliance on land-border crossings highlights a visitor base dominated by regional, short-stay travel. With an average length of stay of just 4.34 days, inbound volume is driven mostly by short visits from Singapore and Indonesia. As revenue per visitor trails long-haul travel markets, upgrading land border infrastructure is a critical strategic lever to expand capacity, extend stay durations, and maximize visitor yield.

Despite rising arrivals, the national hotel occupancy rate sits at only 42.66%, signalling a regional mismatch between supply and demand rather than national overcapacity. This uneven spatial distribution, where popular hotspots operate near capacity while other states sit underutilized, supports the Tourism Gap concept. It also provides clear data evidence for SDG 12 (Responsible Consumption and Production) by prioritizing the efficient use of existing capacity before constructing new infrastructure.

Malaysia's indirect tourism economy, particularly retail and F&B, generates higher spending and employment than direct services like hotels and transport. Because tourism benefits spill over into everyday local businesses, this strengthens the case for community-level investment under SDG 8 (Decent Work and Economic Growth) rather than focusing exclusively on large commercial developments.

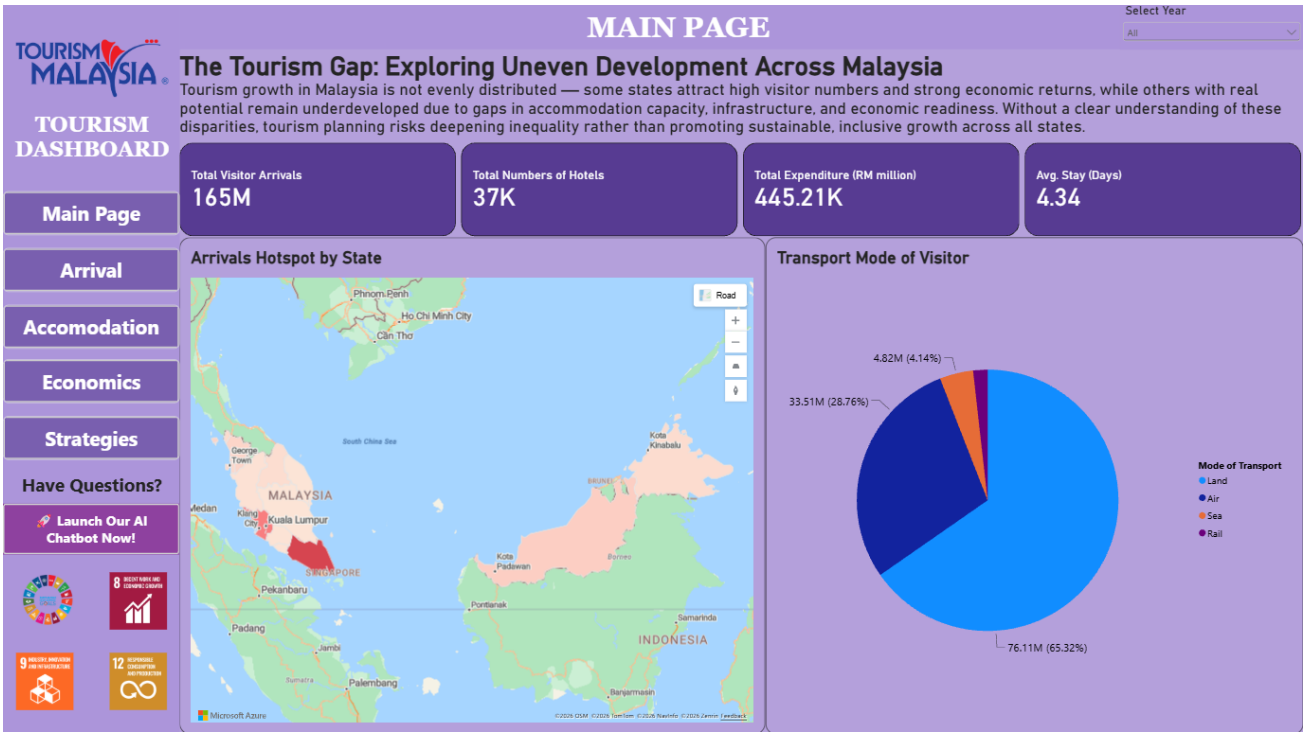

Domestic travellers form the backbone of the sector, accounting for 77.2% of total hotel guests. While this domestic demand provided vital resilience during global travel disruptions, it also creates a growth ceiling. Hitting ambitious Visit Malaysia Year targets will depend on converting high-volume regional land-border traffic into higher-spending international stays.

The dashboard's core policy contribution is the Readiness-versus-Demand quadrant framework. Instead of assuming every high-arrival state is an unqualified success, this matrix separates sustainable growth from regions facing overtourism strain. By offering a targeted, state-specific investment roadmap instead of a generic national strategy, it turns the project into an actionable decision-support tool for SDG 9 (Industry, Innovation, and Infrastructure) and SDG 12.

# DASHBOARD

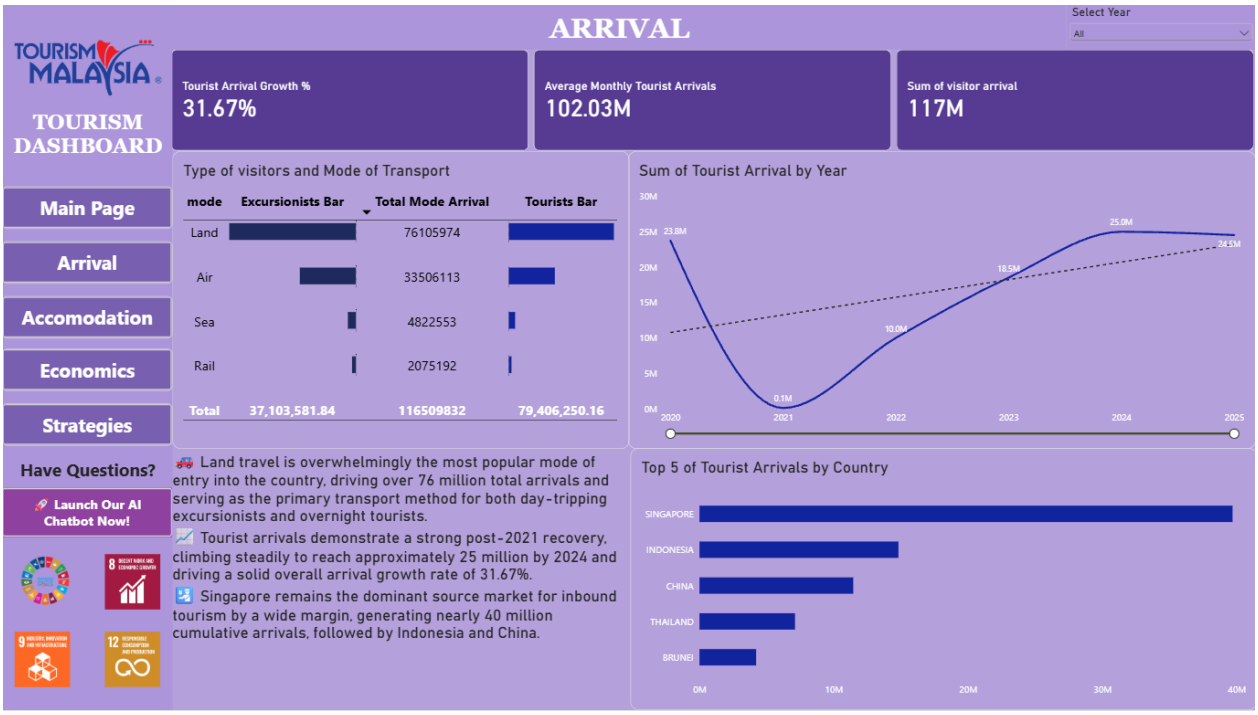

To ensure seamless exploration across the report, the dashboard features a fixed vertical navigation panel on the left side of the canvas. Users can click any page button to transition instantly between the five core analytical sections, enabling an intuitive and structured review of Malaysia's tourism performance across arrivals, accommodation, economic impact, and strategic recommendations.

# CONCLUSION

This project successfully achieved its objectives by providing an integrated analysis of Malaysia's tourism trends, accommodation performance, economic contribution, and future tourism demand. The findings show that tourist arrivals experienced a strong post-pandemic recovery, with arrivals increasing steadily and reaching approximately 25 million in 2024 in the dashboard dataset. Singapore was identified as the dominant source market, while land transportation accounted for the largest share of tourist arrivals.

The analysis also identified a relationship between tourist arrivals and accommodation performance across Malaysian states. Domestic visitors accounted for 77.2% of total accommodation arrivals, compared with 22.8% for foreign visitors. Pahang recorded the highest combined domestic and foreign arrivals among the states displayed. However, the national average hotel occupancy rate was only 42.66%, indicating that accommodation capacity was not fully utilized despite tourism demand.

In terms of economic sustainability, tourism expenditure was distributed across several sectors rather than being concentrated only on accommodation. Country-specific tourism characteristic goods contributed to the largest expenditure share at 34.61%, while accommodation and passenger transport each contributed around 19%. Meanwhile, food and beverage services and retail trade were among the major sources of tourism-related employment. Although employment and expenditure experienced contractions during 2020 and 2021, the dashboard shows a clear recovery in subsequent years.

The machine learning forecast further indicates continued growth in tourist arrivals towards 2027, providing an indication of potential future changes in tourism demand. The strategic position matrix combines projected tourism growth with infrastructure readiness to highlight differences between areas experiencing stronger demand and areas with greater unused potential. These findings support the need to align future tourism development with accommodation capacity, infrastructure readiness, and the distribution of visitors across states.

Lastly, the interactive Power BI dashboard integrates these findings into a single platform covering tourist arrivals, accommodation, economic indicators, forecasting, and strategic insights. Overall, the project demonstrates how data analytics, machine learning, and interactive visualization can support a more balanced and sustainable tourism industry in Malaysia by helping stakeholders understand tourism patterns, monitor economic impacts, anticipate future demand, and identify areas

requiring infrastructure development or better utilization of existing tourism resources.
